Pollard's p-1 Factoization

- Let B be a positive integer. The prime factorization of an integer $n = \prod p_i^{e_i}$. If $\forall i \ p_i^{e_i} \leq B$, n is B-power smooth.
- We wish to find a nontrivial factor of a large positive integer N using the Pollard p-1 method.
- Let us choose a positive integer B. Suppose that there is a prime factor p of N such that $p-1$ is B-power smooth.
- Let us choose $a > 1$ such that p does not divide a. Often we will choose $a = 2$ for convenience.
- By Fermat's Little Theorem $a^{p-1} \equiv 1 \mod p$.
- Let $m = \mathrm{lcm}(1, 2, 3, \ldots, B)$. Since $p-1$ is B-power smooth, $p-1 \mid m \Longrightarrow p \mid \gcd(a^m - 1, N) > 1$.
- If $\gcd(a^m - 1, N) < N$, then $\gcd(a^m - 1, N)$ is a nontrivial factor of N.

Factoring Magic!

- An example of integer factorization using Pollard's p-1 method.
- Let $N = 5917$ and let $B = 5$. $m = \text{lcm}(1, 2, 3, 4, 5) = 60$.
- Let $2^{60} - 1 = 3416 \mod 5917$, and $\gcd(2^{60} - 1, 5917) = \gcd(3416, 5917) = 61$.
- 61 is a factor of 5917!
- But if $p - 1$ and and $q - 1$ (where $pq = N$) are not B-power smooth, Pollard p-1 does not work.
- The issue is that $(\mathbb{Z}/p\mathbb{Z})^*$ has order p-1.

Group Law for Elliptic Curves

- Now we will introduce Elliptic Curves as a group to help solve the integer factorization problem.
- Elliptic Curves are a group under the $\oplus$ operation with the set $\{\mathbb{Z}/p\mathbb{Z}\} \cup \{\mathcal{O}\}$ where $\mathcal{O}$ is the point at infinity.
- The $\oplus$ operation is defined geometrically on two points (x_1, y_1) and (x_2, y_2) thus: draw the secant line and find the third point where it intersects the curve (x', y'), which can include $\mathcal{O}$, finally find $(x', -y')$, the resulting point.
- Under the $\oplus$ operation $\mathcal{O}$ is the identity.
- nb. All computations are done over the set $\mathbb{Z}/p\mathbb{Z}$.
